

Multi-Layer Perceptron (MLP)

* MLP :-

MLP is created by connecting multiple perceptrons together to form a larger Neural Network.

MLPs are mostly used for tabular data but we can use it also for grid structure data (e.g. images) but it works best with tabular data.

* Visual Intuition :-

Imagine two individual perceptrons, each drawing a different decision boundary.

If you superimpose (combine) these lines and apply smoothing you can capture Non-linear relationships.

$$\begin{array}{c} \text{X X O O} \\ \text{X X O O} \\ \text{X X X X X} \\ \hline \end{array} + \begin{array}{c} \text{X X O O} \\ \text{X X O O} \\ \text{X X X X X} \\ \hline \end{array} = \begin{array}{c} \text{X X O O} \\ \text{X X O O} \\ \text{X X X X X} \\ \hline \end{array}$$

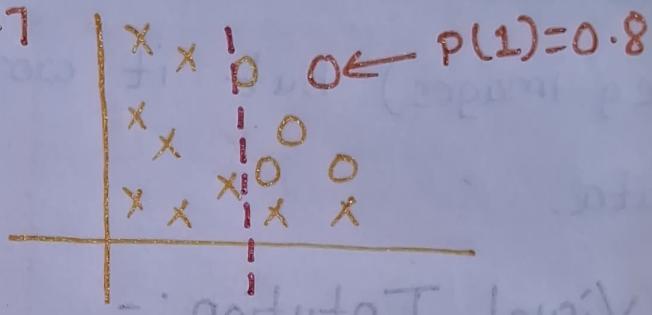

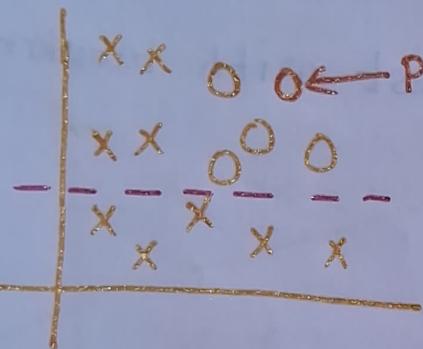

The diagram shows three 3x3 grids. The first grid has 'X' in the top-left, middle-left, bottom-left, and bottom-middle cells. The second grid has 'X' in the top-left, middle-left, bottom-left, and bottom-middle cells. The third grid is the sum of the first two, resulting in 'X' in the top-left, middle-left, bottom-left, and bottom-middle cells, and 'O' in the other four cells.

By combining enough Perceptrons Neural Network can approximate any function allowing it to create

any kind of non-linear decision boundary

* How it works :-

Suppose we are solving 'B Probabilistic Binary classification' problem with two different perceptron models as shown in Fig. We have to find proba. of getting placed of shown point.

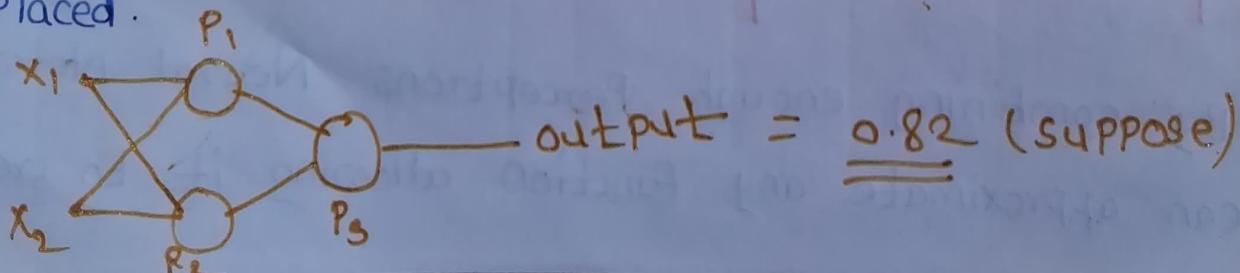

So,

Perceptron 1 \rightarrow P(getting placed i.e 1) = 0.7

Perceptron 2 \rightarrow P(getting placed i.e 1) = 0.8

Now, We create a weighted linear combination of both, and this is the input for next Perceptron having 'Sigmoid' A.F and binary cross entropy as L.F. and predict the proba. of getting placed.

* Network Architecture :-

① Input Layer :- These are the features from the data. They just pass information to next layer.

so, No processing and calculations happens here.
eg: IQ, CGPA etc.

② Hidden Layers :- These nodes are individual Perceptrons, they take input process them and pass output forward.

We call it 'hidden' because it sits between input and output layer.

③ Output Layer :- These layer receives the processed information from hidden layer to generate output or final prediction.
